Quicksort Algorithm

Divide and Conquer

Mergesort and Quicksort both use what's called a “divide and conquer” technique

Divide and Conquer Algorithms

input: list L_{in} to be sorted

output: sorted list L_{out}

divide L_{in} into L_{left} , L_{right}

recursively sort L_{left} into L_{left_sorted}

recursively sort L_{right} into L_{right_sorted}

combine L_{left_sorted} , L_{right_sorted} into L_{out})

The first step is to *divide* the input list, L_{in} into two parts, L_{left} and L_{right} .

Each part is sorted recursively by applying the same divide-and-conquer strategy: the sorted parts are in L_{left_sorted} and L_{right_sorted} , respectively.

The last step is to combine these two sorted parts to produce the sorted list, L_{out} .

In Mergesort, the “divide” step is trivial – just divide the array in two halves. All the work is done in “combine”, where sorted subarrays are merged

Divide and Conquer in Quicksort

In Quicksort, the divide and conquer process works in exactly the opposite way. As in, all the work is done in the “divide” step, and nothing at all is done in the “combine” step.

Algorithm quicksort(A, left, right)

input: subarray $A[\text{left} \dots \text{right}]$

output: sorted subarray $A[\text{left} \dots \text{right}]$

$\text{splitPoint} \leftarrow \text{split}(A, \text{left}, \text{right})$

quicksort(A, left, splitPoint - 1);

quicksort(A, splitPoint + 1, right);

The *split* process selects a *pivot* entry, say x , in the given sublist and rearranges the entries of the sublist in such a way that all the entries less than x are to its left, and all other entries (greater than or equal to x) are to its right.

0	1	2	3	4	5	6	7
15	12	13	11	20	15	22	14

Typically, the first item in the (sub)array is picked as the pivot

Add WeChat powcoder

SPLIT

0	1	2	3	4	5	6	7
13	12	14	11	15	20	15	22
[< 15]				[>= 15]			
Sort recursively				Sort recursively			

After the split, the pivot is in its correct sorted place

Split

Pivot is the first value, 15

Start with L at the next index after the pivot, and R at the last index

Iteration 1

If $A[L] < \text{pivot}$, then advance L to next index, otherwise stop – here L advances all the way to 20, where it stops because 20 is not $<$ than 15

If $A[R] \geq \text{pivot}$, then advance R to previous index, otherwise stop – here R does not advance at all since 14 is not ≥ 15

Swap the values at L and R, then advance L up by 1 and R down by 1, to prepare for next iteration

Iteration 2

If $A[L] < \text{pivot}$, then advance L to next index, otherwise stop – here L does not advance at all since 15 is not < 15

If $A[R] \geq \text{pivot}$, then advance R to previous index, otherwise stop – here R advances to 15

Normally it would have also compared 15, but because it has already been compared via L, R stops without comparing 15 against the pivot.

So the condition to advance R is modified to be:
If $R > L$ and $A[R] \geq \text{pivot}$, then $R--$

At this point, both L and R have finished moving as far as they could,

because R is not $> L$

So we need wrap up. This is done by swapping $A[L-1]$ with the pivot:

Split Example 2

Pivot is 9

Iteration 1

left starts at item 3, right starts at item 12
left moves up to 14 and stops (14 not < 9),

right moves down to 5 and stops (5 not >= 9)
swap 14 with 5, then left++, right--

Iteration 2

left starts at item 7, right starts at item 7
left moves past 7, but stops at 14 without comparing 14
because left has moved past right

So the condition to advance L is modified to this:

If $L \leq R$ and $A[L] < \text{pivot}$, then $L++$

left and right have crossed over, so right does not move at all (remember right only moves if right > left)

All items have been compared against pivot
(right is not > left)
Swap $A[\text{left}-1]$ (7) with pivot (9)

Split: Extreme Case 1 (All items < pivot)

Condition to advance L:

If $L \leq R$ && $A[L] < \text{pivot}$, then $L++$

Condition to advance R:

If $R > L$ && $A[R] \geq \text{pivot}$, then $R--$

Pivot is 15

Iteration 1

L starts at item 12, R starts at item 14

L moves all the way through the array and stops when it moves past R (and goes out of bound)

R does not move at all, since R is not $> L$

Split: Extreme Case 2 (All items \geq pivot)

Condition to advance L:

If $L \leq R$ && $A[L] < \text{pivot}$, then $L++$

Condition to advance R:

If $R > L$ && $A[R] \geq \text{pivot}$, then $R--$

Pivot is 3

Iteration 1

L starts at item 12, R starts at item 14

L does not move at all (since $12 \not< 3$)

R moves all the way across. Pass 16 it goes to item 12, but stops (without making a comparison) because $R \text{ not} > L$

All items have been compared against pivot
(R is not > L)

Swap $A[L-1]$ (3) with pivot (3), i.e. swap pivot with itself

Algorithm `split(A, lo, hi)`

```
    pivot ← A[lo]
    left ← lo+1, right ← hi
    while (true) do
        while (left ≤ right) do
            if (A[left] < pivot) then
                left++
            else
                break
            endif
        endwhile
        while (right > left) do
            if (A[right] < pivot) then
                break;
            else
                right--
            endif
        endwhile
        if (left ≥ right) then
            break
        endif

        swap(A[left], A[right])
        left++
        right--
    endwhile

    swap(A[left-1], A[lo])
    return left-1
```

Algorithm `quicksort(A, left, right)`

input: subarray $A[\text{left} \dots \text{right}]$
output: sorted subarray $A[\text{left} \dots \text{right}]$

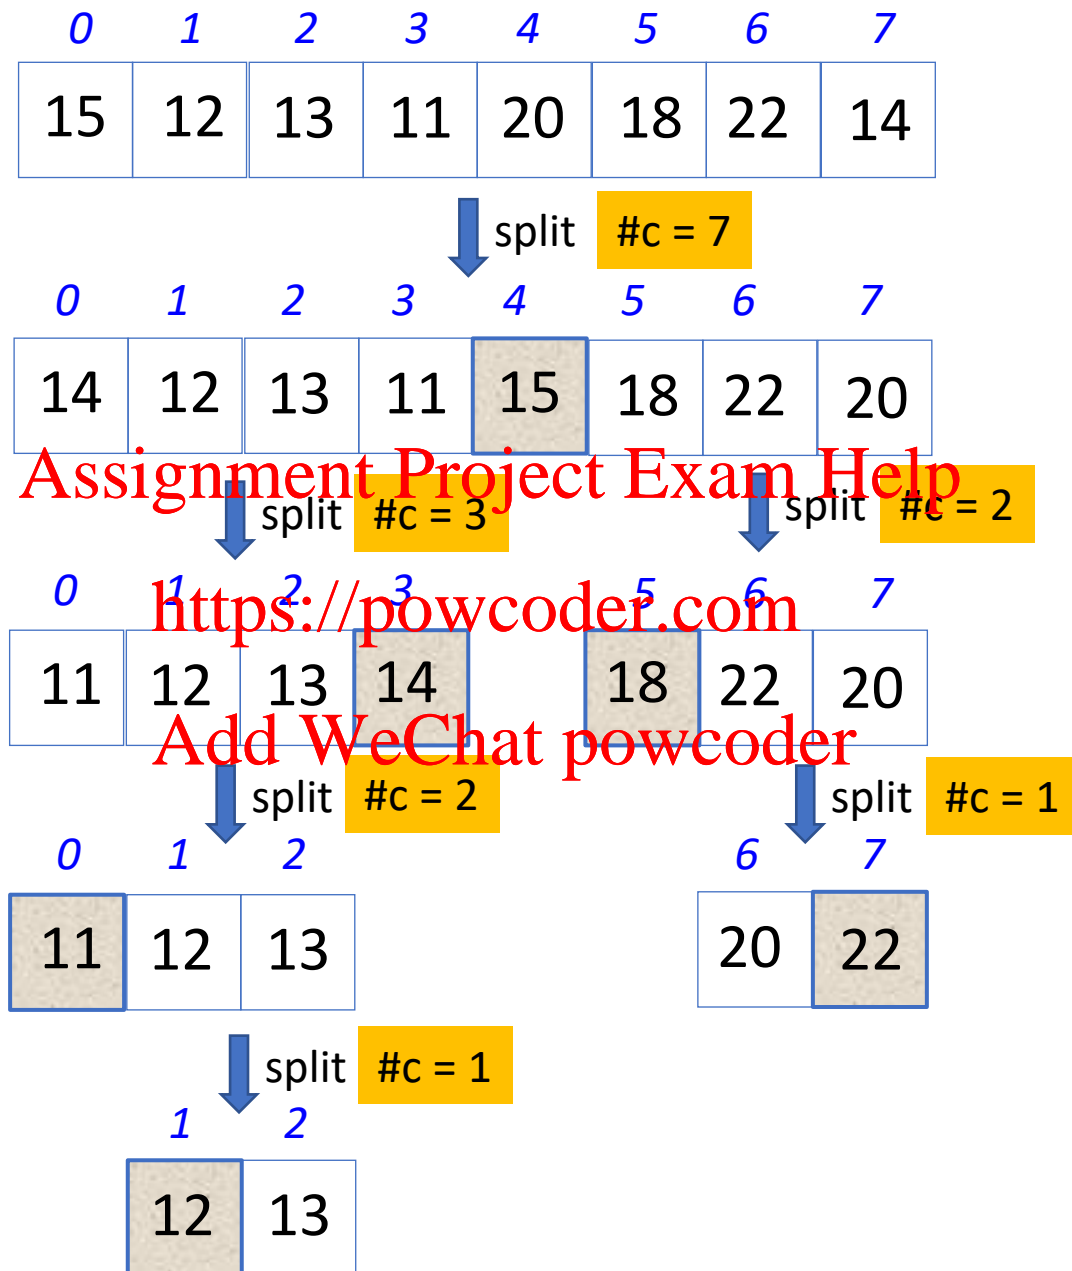

```
    splitPoint ← split(A, left, right)
    quicksort(A, left, splitPoint - 1);
    quicksort(A, splitPoint + 1, right);
```

Total number of comparisons =
 $(n-1) + (n-2) + \dots + 2 + 1 =$
 $n(n-1)/2 =$
 $O(n^2)$

Best case

($n = 16$, the number of comparisons are overcounted somewhat, for ease of analysis but the big O will be unchanged)

Total number of comparisons
= $16 + 16 + 16 + 16 =$
= $16 * 4$ (height)
= $16 * \log_2(16)$

Which generalizes to
 $O(n \log n)$

So why is Quicksort popular?

	Worst Case	Best Case	Average Case
Insertion Sort	$O(n^2)$	$O(n)$	$O(n^2)$
Quicksort	$O(n^2)$	$O(n \log n)$	$O(n \log n)$
